16 1. Executive Summary

17 The world is interconnected by networks, and those networks have become critical to the
18 operation of a broad range of devices and services, ranging from the World Wide Web to
19 industrial robots and the electric power grid.

20 Preserving the integrity and security of equipment such as routers, switches, and firewalls
21 used to create the network infrastructure is essential to network reliability, as well as
22 maintaining integrity and privacy of the many kinds of data that transit networks. As
23 increasingly sophisticated attacks are launched on network equipment, strong protection
24 mechanisms for network equipment, both on the device and service level, is required. Trusted
25 Computing is a key security technology to keep networking services free of disruption and to
26 allow for improvements in maintenance processes.

27 Yet little information is available on how Trusted Computing should be used to secure
28 network equipment and thus the networks that depend on this equipment. TCG’s mission is
29 the creation of security specifications and the promotion of best practices for various
30 application domains. The TCG Network Equipment working group has the expertise to provide
31 good advice in the area of communication devices and the application of Trusted Computing
32 in infrastructure scenarios.

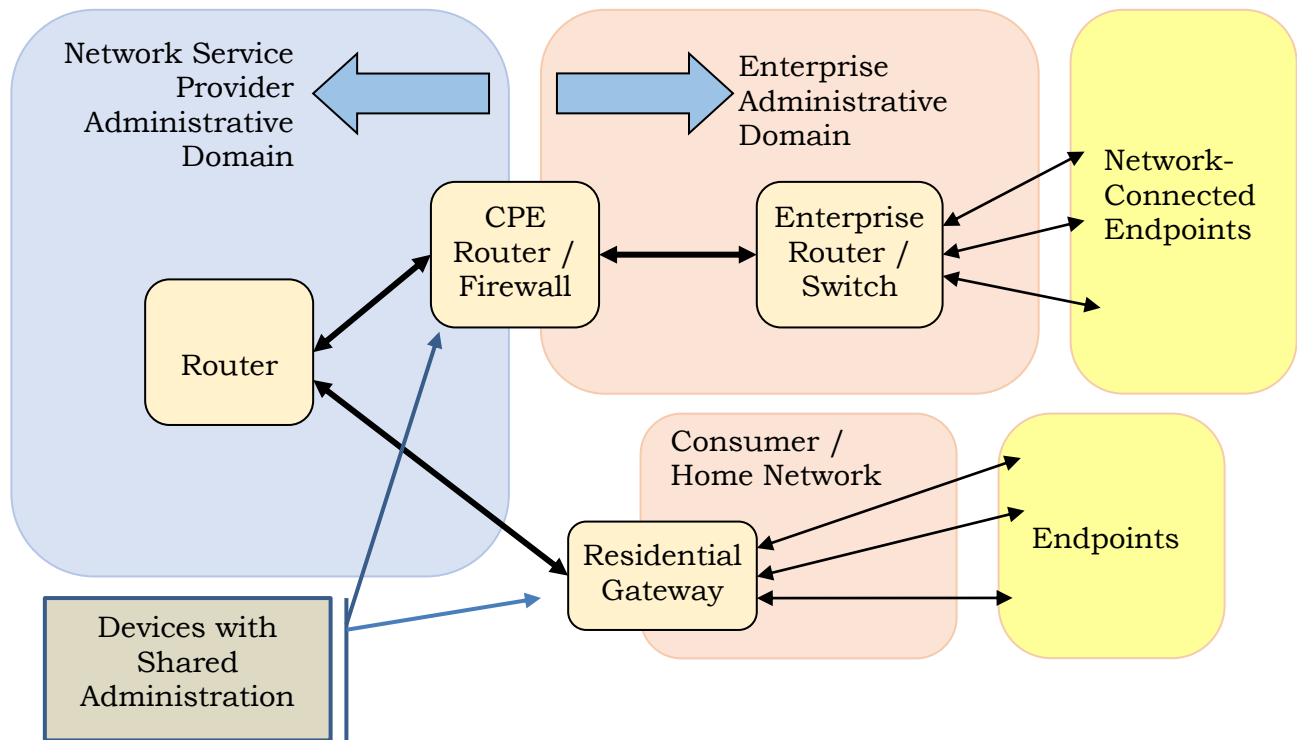

33 The Reference document [TCG Guidance for Securing Network Equipment](#) provides details of
34 use-cases and implementation approaches to solve these problems, designed to help system
35 designers and network architects get the best security possible from this powerful technology.

36 1.1 Network Equipment Reference Model

37 Figure 1 shows a simplified reference model for Network Equipment depicting the stakeholder
38 interactions common in communication networks. Special attention to the interconnections

39 between administrative domains and the protection of end user equipment is important in
40 securing networking equipment.

41 Customer Premise Equipment (CPE) or Residential Gateways are often positioned between
42 administrative domains, and may require special attention for management of access and
43 identity. CPE devices are often under the direct physical access of the respective customers,
44 so secure identities and authentic software are essential security features offered by Trusted
45 Computing.

46

Figure 1: Simplified Network Reference Model

47

48 Traffic transiting from one endpoint to another through networks will often pass through
49 many administrative domains, resulting in a complex trust model. Mechanisms developed by
50 TCG for secure handoff of ownership from one domain to another provide novel security
51 enhancements for the communication industry enhancing the overall robustness of the
52 infrastructure against attackers, and also enabling the detection of common administrative
53 issues.

54 Further, network administrators normally will not have direct physical connectivity to the
55 device, resulting in a need for authenticated remote access to carry out the management
56 functions. Trusted Computing allows for hardware protected device identities whose security
57 is rooted in a certified design, allowing confident use of these identities in remote access and
58 inventory applications.

59 1.2 Key Differences between Network Equipment and PC Applications

60 Networking Equipment almost always contains a general-purpose computing environment to
61 configure and manage the device. But there are distinct differences between Networking
62 Equipment and the common PC client and server applications:

- 63 • While Network Equipment may be highly modular, it is often shipped as a closed
64 embedded system, integrating hardware and software.
- 65 • The chain of security typically does not stop when the OS boots; what matters is
66 security of the networking function that's provided by the unit as a whole
- 67 • Network Equipment typically must boot and operate without manual intervention.
- 68 • While Network Equipment has an important role in protecting user privacy, the
69 equipment itself typically should not have an ability to hide or mask its own identity.
- 70 • Network Equipment often has a long life cycle, and must stay operational in the
71 network for many years.

72 2. Use Cases

73 TCG technology has a number of applications in Networking Equipment, some of which are
74 common to all computing devices, but others of which are unique to the networking
75 application.

76 The *TCG Guidance for Securing Network Equipment* document examines each of these use-
77 cases and provides non-normative advice on how existing TCG technology can be put to use.

78 2.1 Device Identity

79 Providing strong remotely-accessible device identity for each piece of network equipment is a
80 prerequisite for most use cases related to securing network equipment.

81 Following the IEEE *Standard for Local and Metropolitan Networks – Secure Device Identity*,
82 IEEE Std 802.1AR, the *TCG Guidance for Securing Network Equipment* defines Manufacturer
83 device identity and Owner device identity.

84 Manufacturer identity is generally unique across all products from that manufacturer (e.g., a
85 model number plus a serial number), and is cryptographically signed by the Manufacturer,
86 while Owner identity will be unique within the Administrator's facility (e.g., an asset number),
87 and is signed by the Owner of the device.

88 The TCG Network Equipment device identity guidance is aligned with Initial and Local Device
89 ID, as specified in IEEE 802.1AR.

90 Cryptographic device identity has several applications in Networking Equipment

91 **Identity for Network Access** - Telecommunications companies, cloud and data center
92 operators, hospitals, chemical plants, manufacturing facilities are all examples where
93 the network needs to be tightly controlled, and mechanisms used to ensure that only
94 authorized equipment can be connected. This can be achieved by using cryptographic
95 device identification, with keys stored in tamper-resistant TPMs.

96 **OEM Device Identity and Counterfeit Protection** - Both network equipment owners
97 and device manufacturers (OEM's) need to verify the authenticity of network
98 equipment, determining whether it is "counterfeit" (made by an unauthorized party or
99 in an unauthorized manner) or "authentic" (made by authorized parties in an
100 authorized manner). Certificates signed by the manufacturer and rooted in a TPM can
101 provide such assurance.

102 **Secure Zero Touch Configuration** - There are many cases where a networking device
103 may be shipped with no unique configuration, but must be configured before it can be

104 used with a network. Zero Touch Configuration (also known as Autoconfiguration) is
105 an increasingly popular mechanism where the device can identify itself reliably, and
106 communicate through the network, to obtain the configuration information that would
107 specify policy for operational use. As an example, downloaded configuration might
108 enable access to a corporate VPN, by loading a set of private keys.

109 **Remote Device Management** - Network Equipment Owners with a large number of
110 devices often want to manage those devices remotely, including the ability to monitor
111 devices and reconfigure them dynamically. Remote management and reconfiguration
112 is especially important in modern, flexible computing environments that implement
113 Software-Defined Networking (SDN) or Network Function Virtualization (NFV). Reliable
114 identification of each device is critical to remote management.

115 **2.2 Securing Secrets**

116 Network equipment often contains secrets such as traffic logs or cryptographic keys (e.g.,
117 shared secrets, passwords, VPN keys, SSL keys, and stored data encryption keys). Disclosure
118 of these secrets could result in disclosure of confidential network traffic and privacy-sensitive
119 information or even enable malicious tampering with the network. Network operators
120 (especially Service Providers and Enterprises) must protect these secrets against disclosure
121 to keep their networks secure and reliable and also to meet regulatory or customer
122 requirements for confidentiality and privacy, and can use a variety of TPM mechanisms to
123 ensure that private information stays that way.

124 **2.3 Protection of Configuration Data**

125 Network Equipment usually requires configuration, often involving many parameters stored
126 in a variety of files. The equipment Owner may wish to retain control over changes to
127 configuration files on the equipment, with the goal of ensuring that unauthorized
128 configuration changes don't compromise their network. TCG technology can enable an
129 equipment owner to ensure that configuration data can only be applied to the device it's
130 meant for, and can't be snooped along the way.

131 **2.4 Software Inventory**

132 Most Network devices rely on complex embedded software to enable basic features as well as
133 to enforce security policies. This software is often updated on devices already in the field,
134 using releases and patches usually supplied by the device manufacturer, leaving Network
135 Administrators with the task of keeping track of which devices have been updated to what
136 revision level, sometimes tracking many independent components on a single complex device.

137 Mechanisms can be implemented to allow the Administrator to query devices to find which
138 revision level of what components are installed on each network device in their network.

139 **2.5 Attestation of Integrity for Network Devices (“Health Check”)**

140 One extension to remote device management enabled by TCG technology allows the
141 management station to monitor the authenticity of software versions and configurations
142 running on each device, through a process called Attestation. This allows owners and auditors
143 to detect deviation from approved software and firmware versions and configurations,
144 potentially identifying infected devices.

145 **2.6 Inventory of Composite Devices**

146 Many network devices are composed of one or more control or management units plus
147 optional components like line processing units, feature processing units and other kinds of
148 Field Replaceable Units (FRUs), each of which might contain its own autonomous computing
149 environment. The interaction and tasks of the components are vendor specific, but the
150 behavior of the network device is based upon the composite behavior of individual
151 components. The security posture of the network device is therefore only accurately
152 represented by a composite measure that includes the posture of sub-components.

153 Many network devices allow FRUs to be replaced without triggering a complete system restart
154 (often called ‘hot swap’); for these devices, system-level reboots may be very rare, and the
155 system’s security posture must be re-evaluated every time an individual unit is inserted or
156 removed from the system. The *TCG Guidance for Securing Network Equipment* outlines
157 procedures for determining the security posture of these complex machines.

158 **2.7 Integrity-Protected Logs**

159 Various processes in the day-to-day operation of network equipment are based on information
160 gathered from the system status of servers, routers and sensors. SACM, SIEM or even legal
161 interception are based on state information of various components. Tampering with this
162 information, mostly existent as log files, can impact the security protection (e.g. by
163 suppressing intrusion-detection (IDS) data) or impact the integrity of information delivered
164 by the legal interception interface.

165 Integrity-protected log files can be used by the management or external entities by providing
166 information proving the authenticity and integrity of the file.

167 **2.8 Entropy Generation**

168 Many networking protocols such as SSH and IPsec have a need for cryptographic-quality
169 random numbers, to avoid the generation of predictable ephemeral session keys.

170 In addition, the TCP stack for Network Equipment should use good-quality randomness for
171 the TCP window starting point as well as in the selection of ephemeral ports. These help to
172 mitigate SYN and RST attacks against the device.

173 Most TPMs contain a source of cryptographic entropy, which can be used to improve the
174 security of the many mechanisms that depend on random numbers.

175 **2.9 Deprovisioning**

176 Networking Devices often contain information that’s considered sensitive by the
177 Administrator, such as customer configurations or routing policies. Once the device is taken
178 out of service, this information must be reliably destroyed.

179 Confidential information can include TPM keys themselves, or information encrypted by TPM
180 keys. The TPM mechanisms for deleting keys can ensure that the confidential information
181 will become inaccessible.

182 **3. Conclusion**

183 Attacks on network equipment are becoming more frequent and more sophisticated. With the
184 growing importance of networking in our lives, especially as IoT becomes commonplace, the

185 security of network equipment is paramount. While securing network equipment is a complex
186 problem, it is clear that Trusted Computing is essential to provide a firm foundation on which
187 higher-layer security mechanisms can be built.

188

189 The complete *TCG Guidance for Securing Network Equipment* provides detailed
190 implementation suggestions for all of these use cases, plus related background material. The
191 document is currently available for review.

192 Readers interested in this topic (especially network equipment providers and
193 telecommunications carriers) are encouraged to join TCG to help shape this guidance.

194 *TCG Guidance for Securing Network Equipment* can be found on the TCG public web site:
